

# Automatic fitting procedure for the Fundamental Diagram

Victor L. Knoop and Winnie Daamen

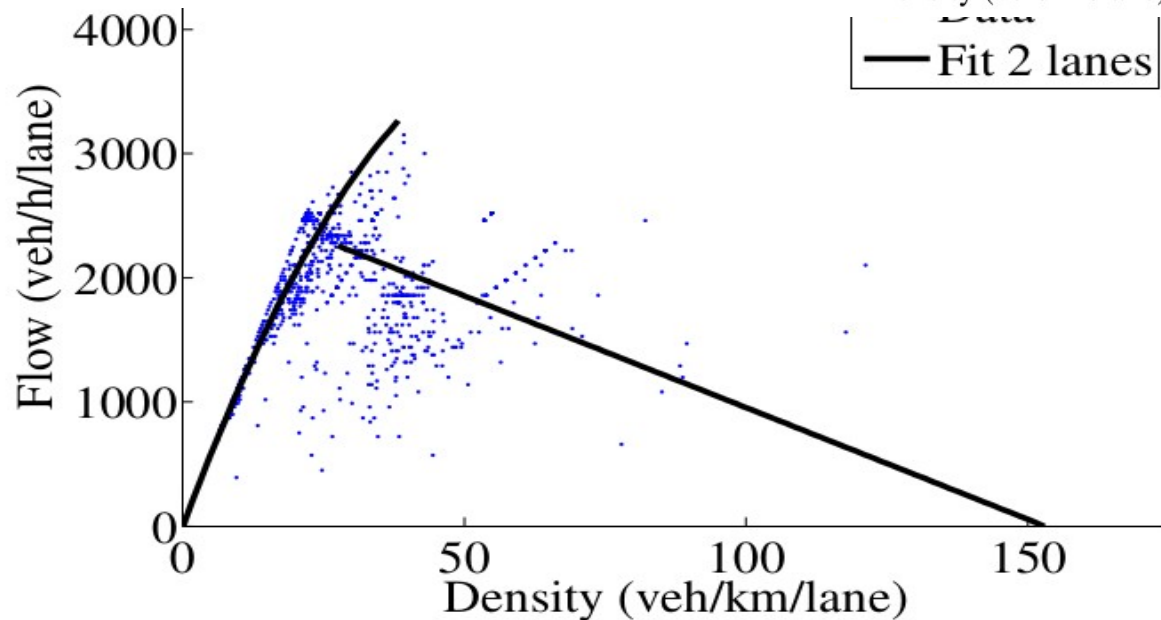

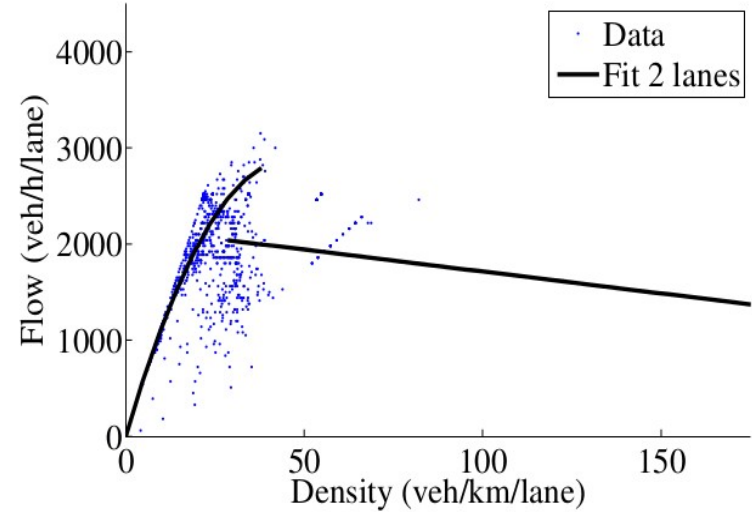

10-08-14

# Fitting fundamental diagrams

- Finding capacity
- Capacity drop
- Scatter
- Erroneous data
- Time mean speeds
  
- Risks:
  - far off

# Fitting fundamental diagrams

# Proposed solution

# Triangular fit

- Weights in the fit

# How to test this procedure?

- Simulation to test quality
- Real data to test robustness
- Fit Wu's fundamental diagram (decreasing free flow speed)
  - different from simulation
  - capacity drop

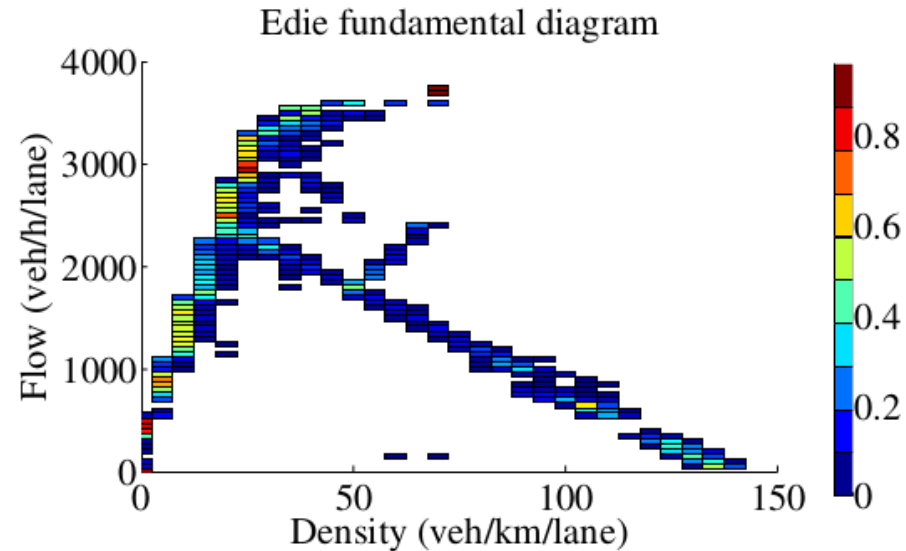

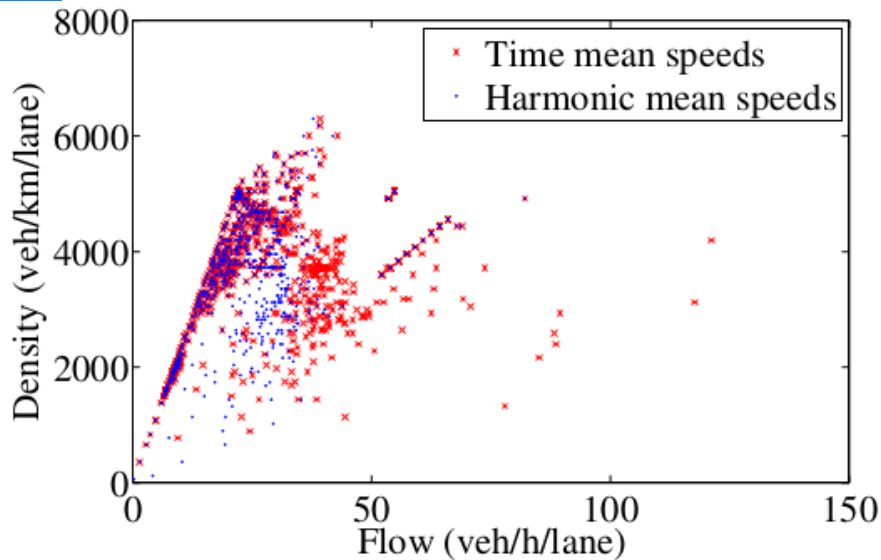

# Simulation

- Single vehicle class
- No driver heterogeneity
- Two lane, on-ramp
- Loops: time mean speed
- Loops: harmonically averaged speed
- Edie defs on parallelogram
- Moving bottlenecks:  
create jams with vehicle speed  $> 0$

# Effect of data collection method

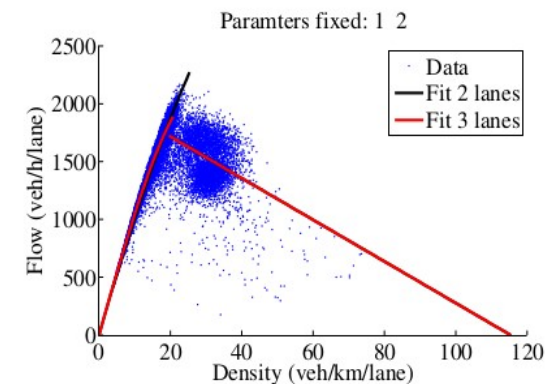

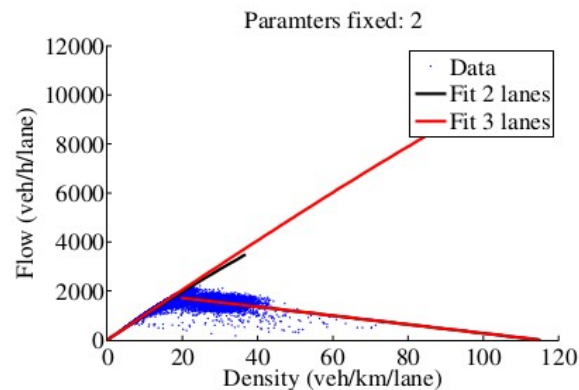

- Data collection method matters, especially in congestion

# Results fitting

- Separation based on triangular FD works
- All parameters free gives bad estimates
- Best: fix the wave speed
  - That is known, so easy to do!
- Fixing free flow speed:
  - fits OK, and more robust for real life data

# Conclusions

- Robust method to fit fundamental diagram
- Separate free flow branch and congestion by triangular fit
- Consider effects of measuring

# Acknowledgement

NWO “there is plenty of room in the other lane”
