

# On the distribution of urban road space for multimodal congested networks

Nan Zheng and Nikolas Geroliminis

Urban Transportation Systems Laboratory (LUTS),  
École Polytechnique Fédérale de Lausanne (EPFL)

# Highlights

- Understand multimodal interactions at the network level
- Model the aggregated dynamics of a multimodal system
- Integrate traffic dynamics in planning and design
- Optimize system performance with space distribution and pricing

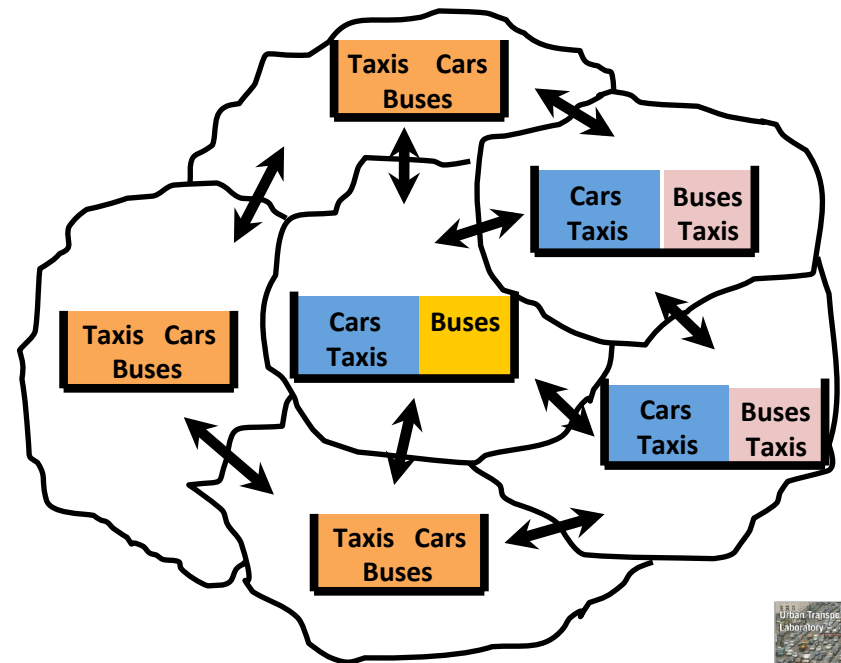

Amount of space required to transport the same number of passengers by car, bus or bicycle.

Car?

Bus?

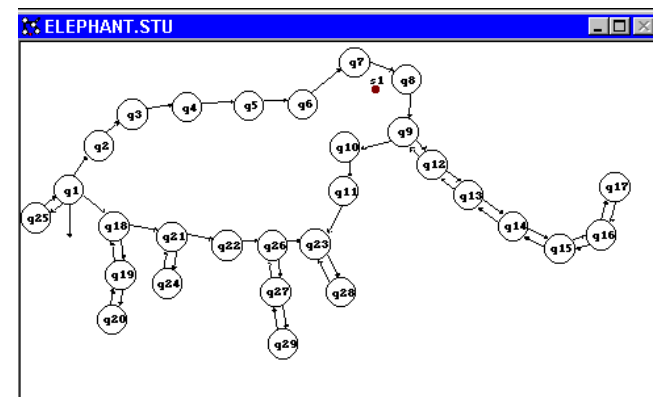

Bicycle?

# Why Macro?

- Humans make choices of routes, destinations and driving behavior (unpredictability)
- Not a clear distinction between free-flow and congested traffic states (complexity)
- Need for real-time hierarchical traffic management schemes (efficiency)

Solution (?):  
A network based aggregated approach

**“With four parameters I can fit an elephant”.  
JOHN VON NEUMANN**

# Multimodal networks

- In urban networks, buses usually share the same network with the other vehicles.
- Movement Conflicts in multi-modal urban traffic systems.
- Bus stops affect the system like variable red signals in a single lane (instead of blocking all lanes).
- Increasing bus frequency decreases the flow of vehicles but can increase the flow of passengers.

$$\min_{\pi_i(t)} Z = \sum_{t,i,m} \text{PHT}_{t,i,m}(\pi_i(t))$$

## Performance Measures

Vehicle Hours Traveled  
Vehicle Kilometers Traveled

Passenger Hours Traveled  
Passenger Kilometers Traveled

## Mobility (Accessibility)

Emissions (Environ. Impacts)

Costs (Users, Providers, etc.)

Road Space Used

- Competing modes
- Parking
- Pax vs. veh throughput

**MULTIMODAL CITIES**

# Motivation – A multi-modal MFD

PASSENGER MFD

VEHICLE MFD

Simulated data – Downtown San Francisco

# Intro to Variational Theory

$$q = \inf_u \{ku + R(u)\} \quad R(u) = \lim_{t_0 \rightarrow \infty} \inf_{\mathcal{P}} \{\Delta(\mathcal{P}) : u_{\mathcal{P}} = u\} / t_0$$

- VT estimates exactly the MFD for a ring with no turns.
- For networks, this estimation is an upper bound
- Results from real cases show that this is almost tight for homogeneous distribution of congestion.

# Methodology - General representation of a multimodal system

$\pi$  : space share allocation

$n(t)$ : accumulation of vehicles (all modes) in the regions at time  $t$

$O(t)$ : transfer flows (all modes) in the regions at time  $t$

$Q(t)$ : generated demand per mode in the regions at time  $t$

$C(t)$ : cost of travel in the regions at time  $t$

# Methodology - Traffic flow dynamics (1)

- Mass conservation of vehicles (discretized):

$$n_i^{kc}(t+1) = n_i^{kc}(t) + \frac{Q_i^{kc}(t+1)}{ob_i^c} - \sum_{j=1}^N O_{i \rightarrow j}^{kc}(t) + \sum_{l=1}^N O_{l \rightarrow i}^{kc}(t), \quad \text{CAR}$$

$$n_i^{kb}(t+1) = n_i^{kb}(t) - \sum_{j=1}^N O_{i \rightarrow j}^{kb}(t) + \sum_{l=1}^N O_{l \rightarrow i}^{kb}(t), \quad \text{BUS}$$

$n_i^{km}(t)$ : accumulation of mode  $m$  in region  $i$  with next destination region  $k$  at time  $t$

$O_{i \rightarrow j}^{km}(t)$ : transfer flow of mode  $m$  from region  $i$  to  $j$  with final destination  $k$  at time  $t$

$Q_i^{km}(t)$ : demand generated  $k$  at time  $t$  in region  $i$  with next destination region  $k$ , choosing mode  $m$

$ob_i^c$ : average number of passengers per car in region  $i$

# Methodology - Traffic flow dynamics (2)

- Conservation of passengers:

$$OB_i^{kb}(t+1) = OB_i^{kb}(t) + Q_i^{kb}(t+1) - \sum_{j \neq i}^N O_{i \rightarrow j}^{kb}(t) \cdot ob_i^{kb}(t) + \sum_{l=1}^N O_{l \rightarrow i}^{kb}(t) \cdot ob_l^{kb}(t) - b_i^k \cdot OB_i^{kb}(t) \cdot (1 - (1 - \theta_i)^z)$$

$OB_i^{kb}(t)$ : the number of bus on-board passengers currently in region  $i$  with final destination  $k$

$ob_i^{kb}(t)$ : the average number of on-board passengers per bus from region  $i$  to  $k$

$b_i^k$ : binary variable indicating if reaching destination,  $b_i^k = 1$  for  $i = k$  and 0 otherwise

$\theta_i$ : probability of reaching destination

$z$ : number of stops that a bus travels during interval  $t$

$\theta_i$  is a Bernoulli trial repeated  $z$  times,  $\theta_i = \left( \frac{\bar{L}'_{ib}}{s_i} \right)^{-1}$ , where  $\bar{L}'_{ib}$  is the trip length  $s_i$  and is the bus station spacing

# Methodology – Multimodal travel time estimation

- Speed estimation for single-mode only region: 
$$V_i^m(t) \stackrel{\text{def}}{=} \frac{P_i^m(t)}{n_i^m(t)} = \frac{O_i^m(t) \cdot \bar{L}_{im}}{n_i^m(t)}$$

- Speed estimation for mixed mode region: 
$$V_i^b(t) = V_i^c(t) \cdot \alpha_i^b(t), \quad \alpha_i^b(t) = \frac{TT_i^b(t)}{TT_i^b(t) + TT_d^b(t)}$$

- Travel time estimation: 
$$TT_i^m(t) = \frac{\bar{L}_{im}}{V_i^m(t)}$$

$V_i^m(t)$ : travel speed of mode  $m$  in region  $i$

$P_i^m(t)$ : travel production of mode  $m$  in region  $i$

$O_i^m(t)$ : Outflow of mode  $m$  from region  $i$  (given by MFD)

$\bar{L}_{im}$ : average trip length of mode  $m$  in region  $i$

$TT_i^m(t)$ : travel time of mode  $m$  in region  $i$  without scheduled stops at time  $t$

$TT_d^b(t)$ : average time spent by bus dwelling for passengers at time  $t$

- Assumptions:

Buses travel with the same speed of cars, if not dwelling for passengers

# Methodology – Mode choice

- Utility of traveling by each mode:

$$U_i^{kc}(t) = - \sum_{j \in \{S_i^k\}} (TT_j^c(t) + C_j^c(t)), U_i^{kb}(t) = - \sum_{j \in \{S_i^k\}} (TT_j^b(t) + D_j^b(t))$$

- Mode choice calculation:

$$p_i^{kb}(t+1) = p_i^{kb}(t) + \beta_1 \cdot \Delta U_i^k(t) + \beta_2 \cdot (\Delta U_i^k(t) - \Delta U_i^k(t-1))$$

$U_i^{km}(t)$  : Utility of traveling by mode  $m$  from region  $i$  to  $k$  at time  $t$

$C_j^c(t)$ : cost other than travel time for using cars in region  $j$  at time  $t$

$D_j^b(t)$  : discomfort for using buses in region  $j$  at time  $t$

$p_i^{kb}(t)$ : percentage of the demand generated at time  $t$  in region  $i$  choosing mode bus

# Methodology – Optimization framework

- System performance measure:

$$PHT(\boldsymbol{\pi}) = \sum_t \sum_i \sum_k (n_i^{kc}(t) \cdot ob_j^{kc} + OB_i^{kb}(t)) \cdot T$$

- Objective function:

$$\min_{\boldsymbol{\pi}_i(t)} Z = \sum_{t,i,m} PHT_{t,i,m}(\boldsymbol{\pi}_i(t))$$

$\boldsymbol{\pi}_i(t)$ : the space distribution plan for region  $i$  at time  $t$

- Optimization algorithm: Lagrangian SQP with multiple initial search

# Case study set-up

- Mixed traffic in periphery
- Dedicated bus lanes in center

# Results - Optimal static space distribution

Space efficiency for all modes (trips/ln-km):

Space efficiency for bus lanes (trips/ln-km):

# Results - Optimal dynamic space distribution

# Results - Optimal dynamic space distribution & pricing

- More reliable MFD states
- TOLL = DELAY SAVINGS
- Robust in demand uncertainty
- Robust in Demand increase

# Results – Demand Increase

# Ongoing work

---

- Deeper analysis of multiple regions
- Incorporating cruising-for-parking + restriction/pricing
- Combining space distribution with signal control, bus priority
- Integrating additional modes
- Validation with field-data
- Heterogeneity among users and different regions
